ABSTRACT: This report aims at evaluation and study the critical behavior of rockfall situated along the roads in the mountainous region. There are approximately ten traffic accidents caused by rockfall in Kochi prefecture every year. Three of them are fatal accidents resulting in death of the drivers and passengers. A field analysis is carried out by studying the geology and tracing the path of rockfall. The motion of rockfall is analyzed based on the data gathered in the field as well as from experiments. The obtained results from the field studies and experiments are compared and the effects of trees on the rockfall motion are evaluated and discussed.

1 INTRODUCTION

The total area of the Kochi Prefecture, shown in Fig. 1, is 7,107km² and its 84% is covered by mountains. The total length of roads in Kochi prefecture is 12,615km consisting of 1,074km national road, 1,063km regional road, 964km prefectural road and 9,515km local road. These roads mainly pass through the steep mountainous region where only

39% of them are improved. The Kochi prefecture, with annual precipitation of 2,600mm, is one of the most heavily rained regions in Japan. Its average monthly precipitation during the rainy and typhoon season exceeds 300mm.

Because of the climate and geography of the region, many rockfall accidents and incidents have been reported every year. In what follows some important of them will be analyzed and discussed.

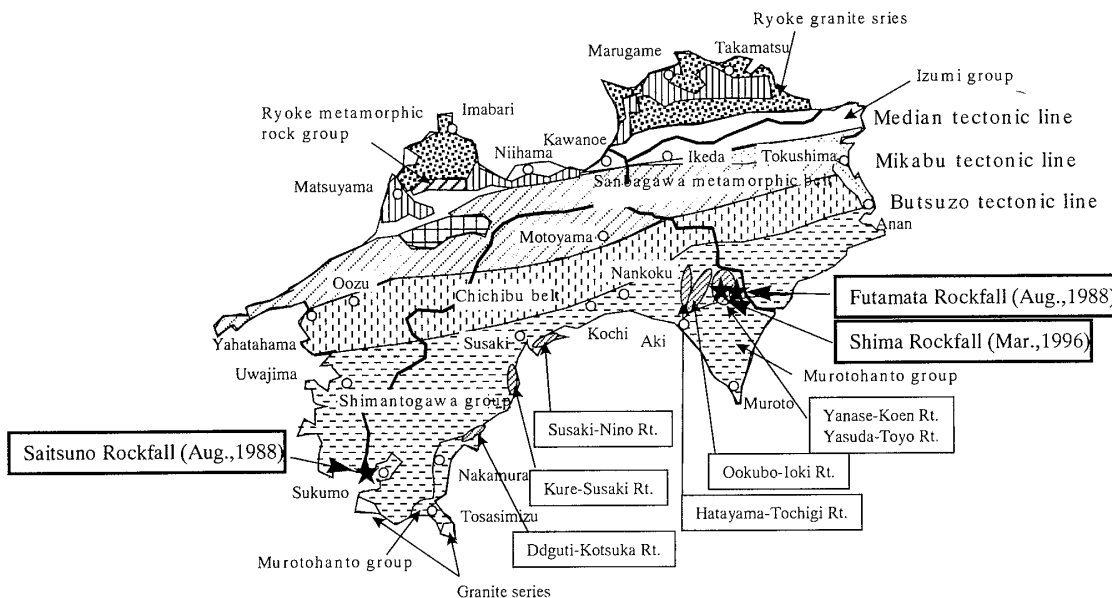

Fig.1 Locations of Accident by Rockfalls in Kochi Prefecture

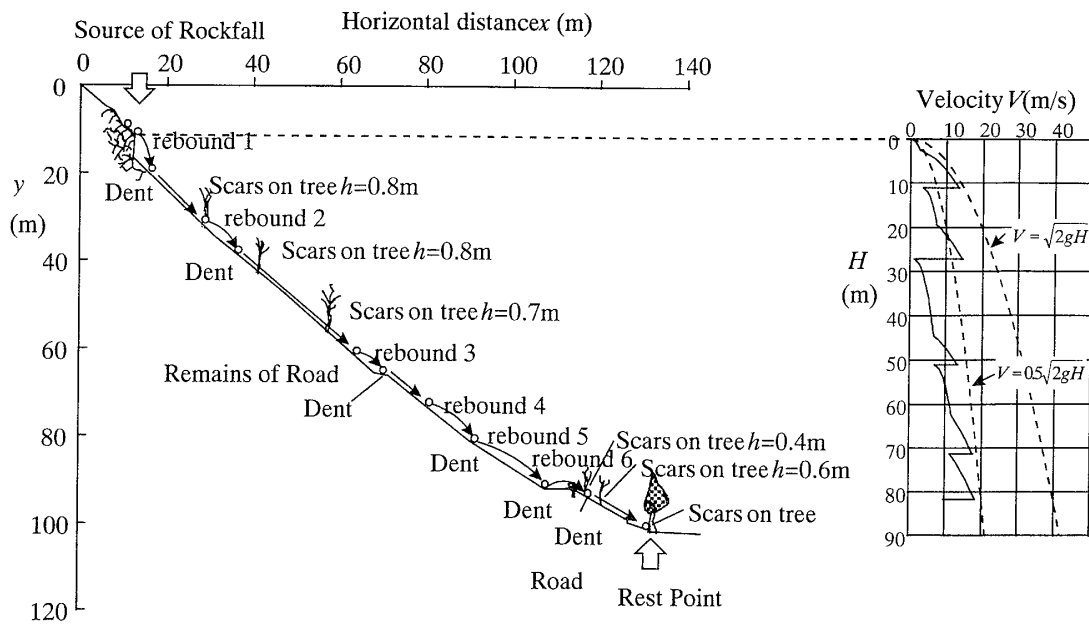

Fig.2 Shima Kitagawa Rockfall

2 SHIMA ROCKFALL (SHIMA, KITAGAWA)

2.1 Overview

At 7:50 am of Mar. 2, 1996, a rockfall of approximately 10 tons hit a car running on the Toyo-Yasuda prefectural road (Route 439). The driver was injured and died after being rushed to the hospital.

The topography of the site is a valley, where the steepness of the slope is 41° up to remains of the road at the height of 25m from the road surface and 36° for the higher points, see Fig. 2.

The geology of the site, which falls into the Shimantogawa group, consists of sandstone and shale. The bedrock is exposed and formed scarp face of 80m above the road. There are many boulders of 0.5~0.8m on the talus slope between the roads and the remains of the roads. Vegetation of the slope is a broadleaf tree of 45 years old. There are also 25~29 years old cedars above the scarp face.

2.2 Source of rockfall

The sandstone block caused the accident had size of $2.6\text{m} \times 1.3\text{m} \times 1.8\text{m}$ (with an estimated weight of 10 tons). It was rested against a cedar tree 18m away from the road.

The source of rockfall was scarp face of 82m above the road and there was evidence that the rock had loosened from it, see Fig. 3. The bedrock was

Fig.3 Source of Rockfall

Fig.4 Deformation Caused by Rockfall

fractured and had open cracks on its surface. The deformation caused by the rockfall is shown in Fig. 4.

Fig.5 Rockfall Accident Diagrams (Rebound 6)

2.3 Mechanics of rockfall motion

Many scars, splits, and shear failure were found on trees along the path. These scars were located less than 1.0 m above the root of the trees. Also 6 dents caused by rockfall were found. A guard fence had been installed along the side of the road and the

Fig.6 Flight Path of Rockfall (Futamata, Kitagawa)

props of the fence were pushed into the ground by 13cm by the impact of rockfall. The beams of fence were deformed to W shape, which matches to the bottom shape of the boulder. This indicates that the boulder jumped over the fence.

There were no slip marks left on the road. Therefore, the boulder hit the running car before the driver could push the break. Impact of the rock on the right side of car at the head-light rotated the car clock wise and left the tail of car hit to the guard fence, see Fig. 4. Figures 2 and 5 show movement of the rockfall estimated from traces and tracks.

3 FUTAMATA ROCKFALL (FUTAMATA, KITAGAWA)

3.1 Overview

At 8:20 am of August 11, 1988, a boulder with an estimated weight of 1.0 ton hit a pickup truck running on the Toyo-Yasuda prefectural road (Route 439). The boulder crushed and killed the driver's wife sitting next to the driver. The driver was seriously injured and hospitalized for 2 months. It was raining at the time of accident. That is, the rock was loosened due to the rain, which was considered the cause of accident.

The geology of the site is Southern Shimanto belt, which consists of sandstone and shale. The slope was covered with 1~2m thick residuals. There were many 0.3m~0.5m boulders on the slope. However, boulders of equal sizes located only over 47m above the road caused the accident. The source of rockfall was 47.6m above the road. There was a scarp face supplying boulders above 20m of the source.

The average steepness of the slope up to 18.1m above the road, where remains of the road existed, was 49° . The average steepness between the remain of road and the source was 41° and it was steeper for higher points. The average steepness between road and the source was 44° . Vegetation of the slope was broadleaf trees for between road and remains of the road. The slope above remains of the road was a forested area consisting of cedars trunk having size of 30cm.

3.2 Mechanics of rockfall motion

The boulder that hit the truck was angular sandstone boulder having size of $1.0\text{m} \times 0.7\text{m} \times 0.55\text{m}$ and estimated weight of 1.0 ton. This boulder left scars on trees along the path. Most scars on the trees were left within 1.1m above ground.

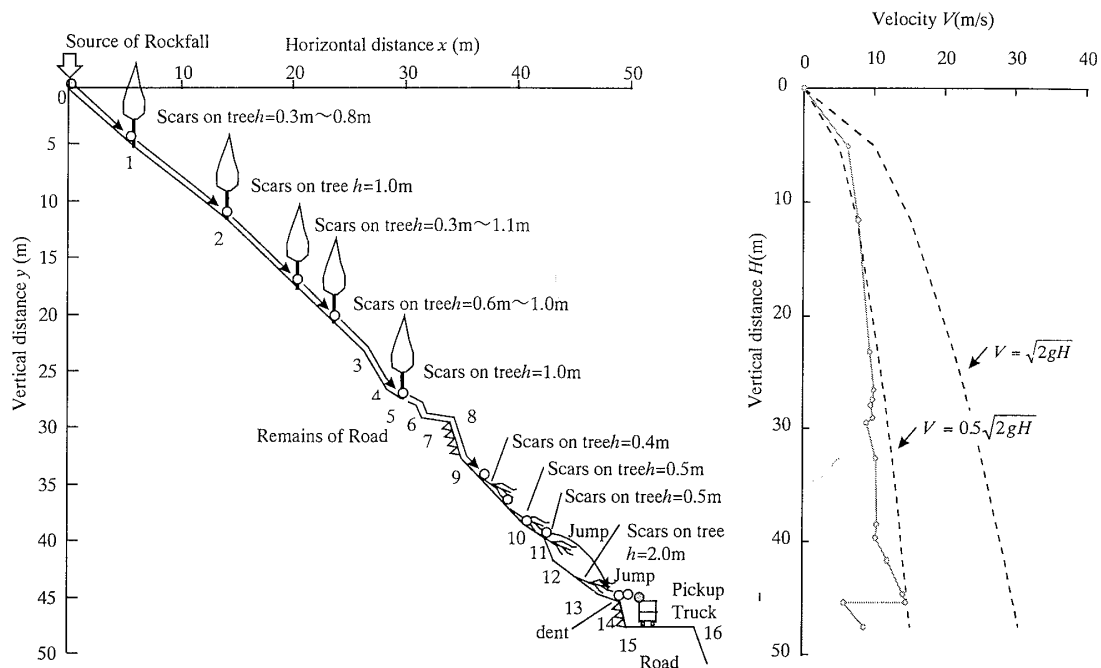

Fig.7 Cross section of Futamata Rockfall Slope

Fig.8 Path of Rockfall

From traces of the rock, it is estimated that the boulder initially rolled or slid on the slope, then jumped at point 11, bounded on the retaining wall, and finally hit the roof of car. There was no dent and therefore no jumping till point 11.

The estimated rockfall path is shown in Fig. 8. The site slope has no significant change and its contour lines are nearly parallel. Therefore, rockfall moved straight but was deflected by trees.

4 SAITSUNO ROCKFALL (SAITSUNO, OTSUKI)

4.1 Overview

At 2:20 p.m. on August 12, 1988, a boulder caused by landslide hit a car running on Route 321. The boulder broke through the windshield, hitting steering wheel, passing through side of the driver's

head, hitting a passenger's head on the left rear seat, and escaped from rear window. The passenger was killed instantly and the driver was seriously injured. There was a heavy rain earlier in the morning, and it loosened the slope and caused landslide and rockfall.

The geology of the slope, with Southern Shimanto formation, consists of sandstone and shale. Its steepness is approximately 53° . Although the slope was densely vegetated by cedars, the boulder passed through sparsely vegetated previous debris.

There was a rockfall prevention work in the site, but there was no prevention work at the location of accident. The reason was probably due to existence of a 5m space between the road (with 3.7m width) and mountain which has given false sense of safety.

4.2 Mechanics of rockfall motion

There were evidences of exfoliation of boulder in the previous debris at 48m above the road, thus this place was considered as source of the rockfall. There were eight sandstone boulders of size $0.5\text{m} \times 0.3\text{m} \times 0.2\text{m}$ and many boulders with diameters of 0.05m - 0.1m in the site. It was concluded that exfoliated boulder disintegrated along the way down on the slope or on the road upon impact. There were broken and scared trees at the passage of rockfall and remains of impact of rockfall were left on the slope. We concluded that rockfall rolled from source, rebounded and rolled on the remain of road, hit retaining wall and jumped, finally hit the car as shown in Fig. 9. It is estimated that the final rebound velocity to be 10.0 m/s and impact velocity to the car to be 12.1 m/s .

5 CHARACTERISTICS OF ROCKFALL ON SLOPES

5.1 Velocity conservation coefficients of rockfall

Figure 2 and Figure 5 shows the estimated velocity of rockfall. We estimated the flight path of rockfall and calculated velocity from 3 points of flight path while rockfall was in the air. We also estimated coefficient of friction on the slope to be $\mu = 0.5$ and resistance of the slope to be C_k , which was constant throughout the slope. We calculated C_k under the conditions of zero initial velocity and no change in velocity when the rockfalls motion changed from a linear (slide or roll) state to a nonlinear (rebound) state. The estimated velocity of the rockfall can be given by the equation 1 as follows:

$$\begin{aligned} \tan \theta &> \frac{7}{2} \mu \\ V &= \frac{g}{C_k} (\sin \theta - \mu \cos \theta) + \left\{ V_0 - \frac{g}{C_k} (\sin \theta - \mu \cos \theta) \right\} e^{-C_k t} \\ \tan \theta &\leq \frac{7}{2} \mu \\ V &= \frac{5g}{7C_k} \sin \theta + \left\{ V_0 - \frac{5g}{7C_k} \sin \theta \right\} e^{-C_k t} \end{aligned} \quad (1)$$

(g = acceleration of gravity, θ = slope angle, t = time) The velocity conservation coefficients $\alpha_v = V / \sqrt{2gH}$ for calculated velocity was $\alpha_v = 0.5$ for Shima and Futamata, and $\alpha_v = 0.75$ for Saitsuno.

Fig.9 Flight Path of Rockfall (Saitsuno, Otsuki)

Figure 10 shows relationship between velocity conservation coefficient α_v and steepness of slope. Data for this figure includes actual rockfall (Kitanada, Ooto) and field rockfall experimental data. All the field experiments were performed on slopes without vegetation cover for easier observation.

When the slope was talus, velocity conservation coefficients of actual slopes were 25% smaller than experimental slopes. This could be the effect of trees. There was no difference in velocity conservation coefficient between actual and experimental slopes for rock slopes. This is because there was less trees on rock slopes thus energy loss by trees was smaller.

5.2 Rebound height of rockfall

Figure 11 shows relationship between estimated rebound height from scares on trees and steepness of slope. Data for this figure includes actual rockfall (Kitanada, Ooto) and field rockfall experimental data. We used maximum rebound height in actual slopes, reduced 95% of average for confident rebound height in experimental slopes.

The rebound heights of actual slopes were 1.0m smaller on talus and 1.5m smaller on rock surface than experimental slopes. This can be explained by energy loss by trees.

6 CONCLUSIONS

From analysis of actual and experimental data, the following conclusions can be drawn from this study:

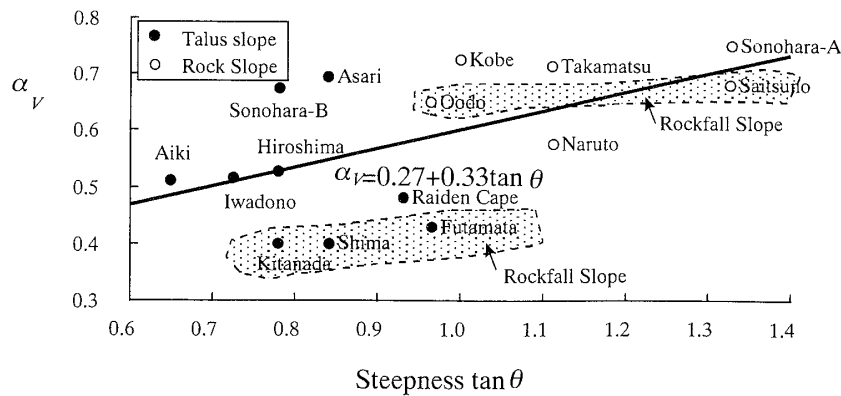

Fig.10 Relationship between Velocity Conservation Coefficient and Steepness

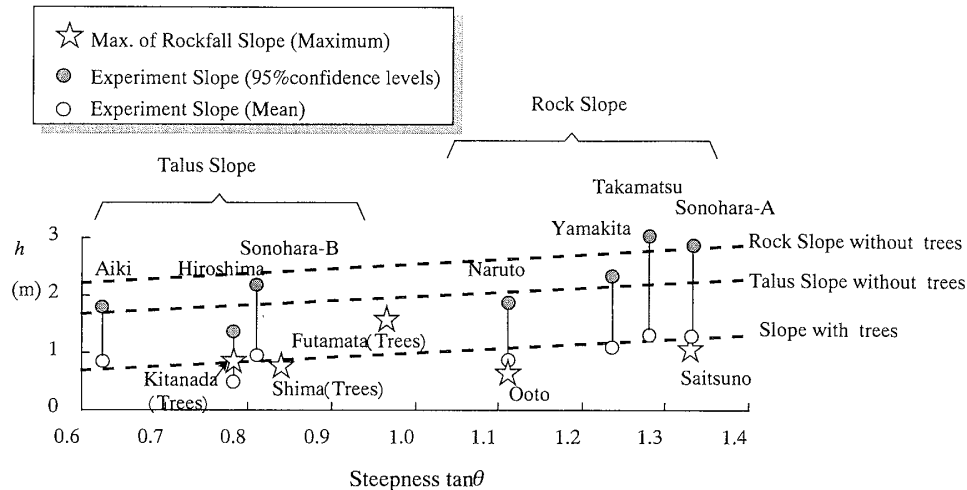

Fig.11 Relationship between Jumping Height and Steepness

1. Actual rockfall slopes had trace of rockfall on trees and surface based on which the rockfall motion can be estimated.
2. Rockfall velocity on actual slope was 25% smaller than the experimental data. This is resulted by energy loss caused by trees.
3. Rebound heights of the actual slopes were 1.0m smaller on the talus slope and 1.5m smaller on the rock slope than those of the experimental slopes. This can be explained by energy loss caused by trees.
4. If there is a flat area such as remain of road on slope, it acts as a jump stand and increases rebound height. That is, it increases the danger.

Slope engineering in Hong Kong

Proceedings of the annual seminar, Hong Kong, 2 May 1997
 1998, 25 cm, 360 pp., EUR 79.50 / \$93.00 / £56

The proceedings contain a keynote paper which describes the risk management of slopes of Hong Kong and an invited paper which presents the state-of-the-art of slope design in Hong Kong. The publication also contains papers with a wide range of topics including case studies, slope hydrology, design and analysis of slopes, application of quantitative risk techniques in slope stability assessment and other special topics. This will be a useful reference book for geotechnical engineers in Hong Kong and other parts of the world dealing with slopes in tropical soils and densely populated areas.

Mechanics of granular materials: An introduction

1999, 25 cm, 400 pp., EUR 88.00 / \$95.00 / £62
 St.edn: paper 90 5410 462 7, EUR 43.00/\$45.00/£30

The main objective of this introductory textbook is to produce a compilation of present knowledge in a readily usable form which will make it easy for graduate students and young geotechnical engineers to understand. The book compiles state of the art reports written by about 35 internationally recognized authorities, and covers the whole range of interests for geotechnical engineers. The book is designed to provide readers with a primary reference source to a particular topic on granular materials.

Granular media are quite common in nature, as well as in industry, so that their related topics have been widely discussed in various fields of science and engineering. The efforts, which are often directed to the establishment of a new field of mechanics, have resulted in many recent developments in theoretical, computational, and experimental researches in this field. More importantly, a variety of excellent papers are still accumulating in widely disseminated journals. Topics: Fundamentals for mechanics of granular materials; Continuum theory of granular materials; Discrete element approaches; New findings from experimental studies; Rapid flow of granular materials; etc.

Griffiths, J.S., M.R.Stokes & R.G.Thomas (eds) 90 5809 078 7
Landslides

Proceedings of the 9th international conference and field trip, Bristol, 16 September 1999

1999, 25 cm, 172 pp., EUR 80.00 / \$85.00 / £56

Topics: An overview of the main landslide field sites in the 9th ICFL; Aspects of recent landslide research at the University of Wollongong; Infiltration of rainwater and slope failure; Landslide hazards and highway engineering in Central and Northern Jordan; El Niño 1997-98: Direct costs of damaging landslides in the San Francisco Bay region; Mass movement features in the vicinity of the town Sorbas, South-east Spain; The movements and the countermeasures of the Choja Landslide; Interest in landslide hazard information - Parallels between Kingston, Jamaica and the San Francisco Bay region, USA; Slide activity in quick clay related to pore water pressure and weather parameters; Old and recent landslides of Barranco de Tirajana basin, Gran Canaria, Spain; etc.

Chacón, J., C.Irigaray & T.Fernández (eds.) 90 5410 832 0
Landslides

Proceedings of the 8th international conference and field workshop, Granada, Spain, 27-28 September 1996

1996, 25 cm, 406 pp., EUR 104.50 / \$123.00 / £74

Landslide description, terminology, classification, inventory and mapping; Landsliding effects and consequences; Landsliding causes: Determining and triggering factors; Slope stability and failure analysis: Treatment and control; Landslide distribution, susceptibility, hazard and risk mapping and assessment; etc. 44 papers. This book is intended for engineering geologists, physical geographers, geologists, geomorphologists, engineers, students and professionals interested in the environmental incidence of landslides as one of the natural hazards.

Robertson, P.K. & P.W.Mayne (eds.) 90 5410 939 4
Geotechnical site characterization

Proceedings of the first international conference, Atlanta, Georgia, 19-22 April 1998

1998, 25 cm, 1496 pp., 2 vols, EUR 132.00/\$154.00/£93

The theme of the conference was to promote the exchange of novel and innovative ideas, new technology and practical applications related to all aspects of site characterization for geotechnical and geoenvironmental engineering. The proceedings contain over 200 papers covering: 6 theme lectures and a major technical report on pressuremeter testing; Planning for site investigations; Site investigation case histories; Sampling; Geophysical testing; Penetration testing; Pressuremeter testing; Dilatometer testing and advanced interpretation. The book provides an excellent source of information, data and ideas related to site characterization for researchers and practising engineers worldwide.

Ochiai, H., N.Yasufuku & K.Omine (eds.) 90 5410 833 9
Earth reinforcement

Proceedings of the international symposium, Fukuoka, Kyushu, Japan, 12-14 November 1996

1996, 25 cm, 1220 pp., 2 vols., EUR 165.00 / \$194.00 / £116

The first volume of the proceedings contains texts of 151 papers selected for the third symposium in 1996. The papers are arranged under five categories which cover almost all aspects in the area of earth reinforcement: Testing and materials; Embankments; Wall structures; Foundations; Slopes and excavations. The second volume contains texts of the special and keynote lectures, texts of the special reports on the performance of earth reinforcement structures under the latest two great earthquakes, reports of technical session chairmen and discussion leaders as well as concluding remarks.
